# Lab 8

## Juliane Kwong

## Breast Cancer Project

Today we are going to explore some data from the University of Wisconsin Cancer Center on Breast biopsy data.

Q. How many patient samples are in this dataset.

```
nrow(wisc.data)
```

#### [1] 569

Use  ${\tt r}$  to include any data from the function when the file is rendered. There are 569 patients in this dataset.

Q. How many cancer (M) and non cancer (B) samples are there?

### table(wisc.data\$diagnosis)

B M 357 212

```
diagnosis <- as.factor(wisc.data$diagnosis)
#diagnosis</pre>
```

Now exclude the diagnosis column from the data

head(wisc.data[,-1])

Q. How many "dimensions", "variables", "columns", are there in this dataset?

ncol(wisc)

[1] 30

## Principal Component Analysis (PCA)

To perform PCA in R we can use the prcomp() function. It takes as input a numeric dataset and optional scale=FALSE/TRUE argument.

We generally always want to set scale=TRUE but let's make sure by checking if the mean and standard deviation values are different across these 30 columns.

#### round( colMeans(wisc))

```

plot(pca\$x[,1], pca\$x[,2], col=diagnosis)

```
library(ggplot2)

x<-as.data.frame(pca$x)
ggplot(x) +
  aes(PC1, PC2, col="diagnosis") +
  geom_point()</pre>
```

pca<-prcomp(wisc, scale=TRUE)</pre>

Q. How much variance is captured in the top 3 PCs.

They capture 76% of the total variance.

Q9. For the first principal component, what is the component of the loading vector (i.e. wisc.pr\$rotation[,1]) for the feature concave.points\_mean? This tells us how much this original feature contributes to the first PC.

```
pca$rotation["concave.points_mean",1]
[1] -0.2608538
```

## Combine PCA results with clustering.

We can use our new PCA variable (i.e the scores along the PCs contained in t pca\$x) as in put for other methods such as clustering.

```
# Hclust needs a distance matrix as input
d<-dist(pca$x[,1:3])
hc<-hclust(d,method="ward.D2")
plot(hc)</pre>
```

### **Cluster Dendrogram**

d hclust (\*, "ward.D2")

To get our cluster membership vector we can use the cutree() function and specify a height (h) or number of groups (k).

```
grps<-cutree(hc,h=80)
table(grps)

grps
1 2</pre>
```

203 366

I want to find out how many diagnosis "M" and "B" are in each grp

```
table(diagnosis)
```

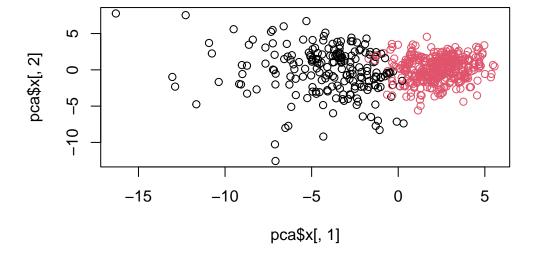

diagnosis B M 357 212

table(diagnosis, grps)

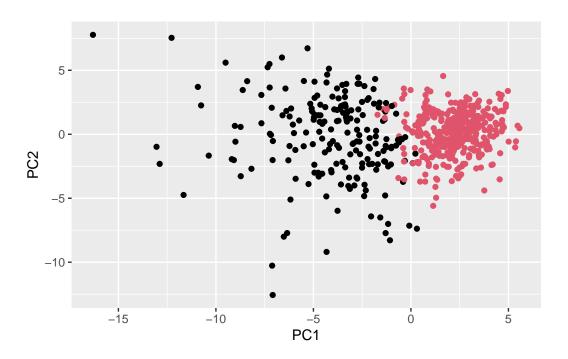

grps diagnosis 1 2 B 24 333 M 179 33

We can also plot our results using our clustering vector grps.

```
plot(pca$x[,1],pca$x[,2],col=grps)
```

```
ggplot(x)+
aes(PC1, PC2)+
geom_point(col=grps)
```

Q15. What is the specificity and sensitivity of our current results?

```
grps
diagnosis 1 2
B 24 333
M 179 33
```

table(diagnosis, grps)

```
M 179 33

# TP refers to benign cases, and TN refers to malignant.

# FN refers to malignant but predicted to be benign. FP refers to benign but predicted to TP <- 33
FN <- 179
TN <- 24
FP <- 333
sensitivity <- TP/(TP+FN)
specificity <- TN/(TN+FN)</pre>
```

```
sensitivity
[1] 0.1556604
specificity
```

## Prediction

[1] 0.1182266

We will use the predict() function that will take our PCA model from before and new cancer cell data and project that data onto our PCA space.

```
#url <- "new_samples.csv"
url <- "https://tinyurl.com/new-samples-CSV"
new <- read.csv(url)
npc <- predict(pca, newdata=new)
npc</pre>
```

```
